## 2 Chapter 9: Sorting in Linear Time

### 2.1 Counting Sort

(a) Rank each element

i. Count how many times  $i$  occurs

ii. Prefix sum on counter array to find how many items  $\leq i$

(b) Place at its location.

Start from right, place item in the output array, decrease its corresponding count.

$W(n) = O(n)$  if range is  $O(n)$ .

**Stable sorts** – counting sort, mergesort, Insertion sort, Bucket sort.

**Nonstable sorts** – Quicksort, heapsort.

---

## 2.2 Bucket Sort

$k$  Buckets.

Algorithm:

1. hash items among buckets
2. sort the buckets
3. Combine buckets

Let there be  $k$  buckets,  $n$  items

1. distribution  $O(n)$
2. sort the buckets
$$w(n) = O(n \log n)$$
$$A(n) = O(k \frac{n}{k} \log \frac{n}{k}) = O(n \log(n/k))$$
3. combine buckets  $O(n)$ .

Thus, bucket sort is

$$w(n) = O(n \log n)$$

$$A(n) = O(n \log \frac{n}{k})$$

If  $k$  is constant,

$$\begin{aligned} A(n) &= O(n \log n - n \log k) \\ &= O(n \log n) \end{aligned}$$

$$A(n) = O(n) \text{ if } k = n/20, A(n) = O(n)$$

Good when item distribution is known so that bucket get equitable number of keys.

## Space Usage

worst-case: each bucket should have space for  $n$  key (any allocation)

$$\Rightarrow \text{total} = O(nk)$$

Thus, as  $k$  increases, average space increases but so does the space requirement.

If linked allocation is used

$$\text{Space needed} = O(k) + O(n) = O(n + k) = O(n)$$

However sorting each bucket using quicksort, mergesort, and heapsort will be difficult which require array representation.

If insertion sort is used to sort linked list, (buckets),

$$A(n) = O\left(\frac{n^2}{k^2}\right) * k = O\left(\frac{n^2}{k}\right) = O(n) \text{ for } k = O(n).$$

Pseudocode

---

## 2.3 Radix sort

for  $i \leftarrow 1$  to  $d$

stable sort  $A$  on digit  $i$ .

- (a) counting sort can be used
- (b) bucket sort can also be used

Pseudocode
